This study was presented in part at the 5th International Consensus Conference on Concussion in Sport in Berlin 2016, and some of these results were published with the conference proceedings.

Received 28 March 2017 Revised 8 January 2018 Accepted 2 February 2018 Published Online First 2 March 2018 ABSTRACT

**Objective** To evaluate the evidence regarding (1) factors affecting return to school (RTS) and (2) strategies/ accommodations for RTS following a sport-related concussion (SRC) in children and adolescents. **Design** A systematic review of original studies specifically addressing RTS following concussion in the paediatric and sporting context.

**Data sources** MEDLINE (Ovid), Embase (Ovid), PsycInfo (Ovid) electronic databases and the grey literature OpenGrey, ClinicalTrials.gov and Google Advanced. **Eligibility criteria** Studies were included if they were original research on RTS following SRC in children aged 5–18 years published in English between 1985 and 2017.

**Results** A total of 180 articles were identified; 17 articles met inclusion criteria. Several factors should be considered for RTS after concussion, including: symptomatology; rest following injury; age/grade; and course load. On RTS after concussion, 17%–73% of students were provided academic accommodations or experienced difficulty with RTS. Students were more likely to obtain academic accommodations in schools with a concussion policy if they had a medical RTS letter and had regular medical follow-up after concussion.

**Conclusions** Schools should have a concussion policy and offer individualised academic accommodations to students recovering from SRC on RTS; a medical letter should be provided to facilitate provision/receipt of academic accommodations; students should have early, regular medical follow-up following SRC to help with RTS and monitor recovery; students may require temporary absence from school after SRC; clinicians should assess risk factors/modifiers that may prolong recovery and require more intensive academic accommodations. **PROSPERO registration number** CRD42016039184.

## INTRODUCTION

Concussions are common in sports, particularly in children and adolescents, with about 70% of sport-related head injuries occurring in persons under 18 years of age.<sup>1</sup> About 100000–175000 children present annually to US emergency departments (ED) with sport-related concussion (SRC), which accounts for 25%–50% of paediatric concussions.<sup>2–5</sup> Concussions represent 9%–12% of sport injuries in high school athletics.<sup>67</sup>

Children face different issues than adults after SRC, with RTS being a key aspect of management. For children and adolescents who recover quickly from SRC, school return may require minimal support. However, postconcussion cognitive symptoms such as impaired memory, attention and concentration, and somatic symptoms such as headaches, dizziness and fatigue may negatively impact students' ability to RTS.<sup>8-10</sup> Students with more numerous/severe symptoms may have symptom exacerbation with RTS.<sup>11</sup>

Several consensus/position statements and guidelines have addressed RTS after concussion.<sup>12–16</sup> Following the Fourth International Consensus Conference on Concussion in Sport, the Child-SCAT3 assessment tool was developed for children aged 5–12 years, with a child-specific symptom scale and recommendations for RTS. The Concussion in Sport Consensus Statement also addressed children's cognitive requirements and need for school accommodations.<sup>17</sup> However, these resources have been based on limited empirical research. Many areas of RTS lack evidence-based guidelines.

Therefore, this systematic review addressed two questions:

- 1. What factors must be considered in 'return to school' following concussion?
- 2. What strategies or accommodations should be recommended in 'return to school' following concussion?

## METHODS

This systematic review was conducted as part of a larger review on differences in concussion management between children and adults, which was presented at the Fifth International Consensus Conference on Concussion in Sport.<sup>18–20</sup> However, it represents a more detailed analysis of RTS in children and adolescents following SRC.

This systematic review was prospectively registered in the PROSPERO database (registration number CRD42016039184).

## Literature identification

The search strategy (box 1) was developed in collaboration with a specialist librarian. Electronic databases searched were Ovid MEDLINE, Ovid Embase and Ovid PsycInfo, in addition to reviewing reference lists of retrieved articles and published articles by the authors to identify any potentially eligible articles not identified by the electronic database search. Three grey literature repositories (Open-Grey, ClinicalTrials.gov and Google Advanced) were searched. The searches addressing both

questions (factors and accommodations) were run concurrently; however, the results were analysed separately.

# Article selection

Inclusion criteria were:

- original research on RTS following SRC
- ▶ in children aged 5 years to less than 18 years
- published in English
- between 1985 and May 2016 (results presented at the Berlin meeting).

The search was repeated for this updated review to include studies published between the initial search and June 2017. Exclusion criteria were:

- studies of moderate/severe traumatic brain injuries
- patients with no clear history of head trauma or SRC
- patients who sustained non-accidental injury
- ▶ preschool-age children.

Studies evaluating patients with mixed mechanisms of injury were included if SRC was part of the study population. As well, studies with mixed age cohorts were included if there were sufficient numbers of children/adolescents less than 18 years of age. In addition, studies examining cognitive activity/rest or cognitive impairment following SRC were included as a proxy for school effects following concussion.

All titles and abstracts identified by the search were reviewed independently by two of the authors (LKP and GAD) and the full texts of all potentially eligible articles were obtained and reviewed. The final selection of articles was determined by consensus among the authors.

## Data extraction

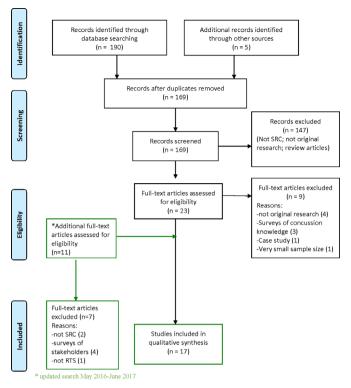

The following data from the included studies were inputted into a data extraction table independently by LKP and GAD: study design; participant characteristics; exposure/intervention; outcome; results; limitations.

# Risk of bias assessment

Two authors (LKP and GAD) independently assessed the quality of each study using the Downs and Black (DB) checklist.<sup>21</sup> This tool can be used for randomised and non-randomised study designs. Discrepancies in DB scoring were resolved by consensus. The level of evidence for each study was assessed independently by each of the authors using The Oxford 2011 Levels of Evidence.<sup>22</sup> All authors agreed on the assessed levels of evidence.

# RESULTS

Seventeen studies were included (figure 1).<sup>23–39</sup> The initial search generated 167 potentially eligible articles of which 11 met inclusion criteria.<sup>23–27 29 30 34–37</sup> Two additional studies were independently identified by one of the authors (GAG).<sup>38 39</sup> The updated search identified 10 additional potential articles, of which three<sup>28 32 33</sup> met inclusion criteria, and an additional article was identified by one of the authors (GAG).<sup>31</sup> Many of the included studies evaluated mixed cohorts of children, adolescents and adults, as well as varied mechanisms of injury not related to sport. Frequent areas of limitations for the included studies included: lack of reported adverse events; external validity for most studies as the populations studied were recruited from urban EDs or specialty concussion clinics; lack of blinding and randomisation. In addition, the overall level of evidence was low (3 or 4); there were only two randomised controlled trials (RCT) identified.<sup>36 38</sup>

**Figure 1** Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) flow diagram. RTS, return to school; SRC, sportrelated concussion.

#### Factors to be considered on RTS following concussion

Eleven articles examined factors to be considered after concussion on RTS (table 1).<sup>23–33</sup> These factors include:

- 1. Symptom load/severity: Higher symptom loads and more severe symptoms were associated with a greater likelihood of missing more days of school and having difficulties on RTS, in addition to longer recovery.<sup>23 25 29-31</sup>
- 2. Types of symptoms: Symptoms such as headache, visual disturbances, memory deficits, difficulty concentrating, executive dysfunction and vestibular abnormalities may adversely affect a student's ability to attend school after a concussion.<sup>23</sup> <sup>25–27</sup> <sup>29</sup> <sup>31</sup>
- Duration of symptoms: Patients with longer duration of symptoms had more difficulty with RTS<sup>23 30</sup>; high cognitive loads after injury were associated with persistent symptoms.<sup>24</sup>
- 4. Age/grade or school level: Adolescents/high school students tended to have more postconcussion symptoms, greater severity of symptoms, and took longer to recover, to RTS and to return to play (RTP) than younger children.<sup>25 29–31</sup> In addition, adolescents were more concerned about negative academic effects of concussion than younger children.<sup>30</sup>
- 5. Course load: Certain subjects such as math pose greater problems for students on RTS after a concussion, followed by reading/language, arts, science and social studies.<sup>30</sup>
- Rest following injury: Patients who did not initially rest following injury took longer to RTS than those who rested immediately following injury<sup>32</sup>; high cognitive loads/increased school attendance exacerbated symptoms.<sup>24 28</sup>

Socioeconomic status (SES) may also affect concussion recovery. A US pilot study examining SES and effect on concussion recovery found that patients with private insurance missed more days of school following concussion than patients with public insurance (mean of 5.2 days $\pm$ 10.6 vs 2.0 days $\pm$ 2.1).<sup>33</sup>

Additional factors to be considered include school concussion policies/resources, medical guidance to schools following concussion diagnosis and medical follow-up after concussion.<sup>36 37 39</sup>

## Strategies or accommodations for RTS

Six articles examined strategies or provision/receipt of accommodations for RTS (table 2).<sup>34–39</sup> Other than temporary school absence, the types of academic accommodations provided were not specified. Most students were able to RTS after 2-5 days, 29 37 38 although up to 45% of students may experience exacerbation/ recurrence of symptoms on RTS.<sup>34</sup> On RTS after concussion, 17%-73% of students were provided academic accommodations and/or experienced school difficulty.<sup>23</sup> <sup>25</sup> <sup>26</sup> <sup>29</sup> <sup>35</sup> <sup>37</sup> <sup>39</sup> An RCT found that academic accommodations were more likely to be initiated for students recovering from concussion in schools with concussion policies.<sup>36</sup> Concussed students who received outpatient medical follow-up, parental education and a medical RTS letter after initial assessment in an ED were also more likely to receive academic accommodations on RTS.<sup>37 39</sup> Some academic subjects, such as mathematics and reading/language, may pose greater problems for students on RTS following a concussion, suggesting that these subjects might require more intervention.<sup>30</sup>

#### DISCUSSION

#### Factors to be considered on RTS following concussion

Although historically concussion management has focused on return to sport, RTS is more important in children and adolescents, since school is their primary 'work'.<sup>40</sup> Four factors should be considered on RTS after concussion<sup>23–33 36 37 39</sup>:

- 1. symptomatology
- 2. age/school level
- 3. course load
- 4. rest following injury.

Students with more symptoms, greater symptom severity, more persistent symptoms and particular symptoms such as difficulty concentrating, executive dysfunction, visual deficits and vestibular abnormalities took longer to recover and had more difficulty with RTS.<sup>23 25 26 29–31 35</sup> Visual abnormalities and vestibulo-ocular abnormalities are particularly common after concussion and in patients with persistent symptoms.<sup>41–45</sup>

Adolescents/high school students tended to have more symptoms, more severe symptoms and more difficulty with RTS than younger students, and took longer to recover.<sup>29 30 34 39</sup> Age 13 years old and greater was a predictor of persistent concussion symptoms in a recent prospective, multicentre ED cohort study.<sup>46</sup> The reasons for age and school level differences are unclear but may reflect the nature of injury manifestation in adolescents; increased academic and social demands; greater challenges to implement consistent, coordinated management strategies across multiple classes/teachers; and greater independence and decreased supervision in compliance with medical recommendations. These studies, however, sampled children and adolescents from specialty clinics, which may represent an overall higher symptom burden and severity, and therefore may limit the generalisation of their findings.

Lack of rest, both cognitive and physical, immediately following concussion has also been associated with persistent symptoms. Higher cognitive activity, such as school attendance, may cause exacerbation of symptoms and prolonged recovery from concussion, as well as longer RTS.<sup>11,24,28,32</sup> Student-athletes who continued to play after injury took twice as long to recover and were almost nine times as likely to have prolonged recovery

(>21 days) compared with those who were removed from play immediately after injury.<sup>47</sup> Although RTS was not specifically assessed, cognitive performance was lower and symptoms higher in adolescents not removed from play immediately after concussion.<sup>47</sup> The presence of risk factors/predictors of persistent symptoms should prompt practitioners to be more cognisant of potential difficulties in RTS and the need for more support in the RTS process.

An additional factor possibly affecting RTS after concussion is SES, though it requires more detailed study to fully understand its significance. The type of family insurance (private vs public), as a proxy for SES, may impact length of school absence following concussive injury, with concussed student-athletes with private insurance.<sup>33</sup> The reasons for this difference in school attendance were not identified; however, the study population represented only about 40% of the cohort and 90% had private insurance, raising concerns about external validity and selection bias. As well, five other markers of SES were not associated with differences in recovery, which makes the significance of SES in concussion recovery unclear.

Very likely there are other factors and specific deficits after concussion, such as autonomic dysfunction, that may impact on RTS that have not yet been studied in that context.

#### Strategies or accommodations for RTS

Significant numbers of symptomatic students (17%-73%) may require academic accommodations on RTS after concussion<sup>29 35 37 39</sup>; however, it is encouraging that a recent study found minimal long-term effects of concussion on academic performance in high school at a population level.<sup>48</sup> A range of strategies/accommodations to support RTS following concussion have been proposed, including temporary school absence.<sup>12-16 35-37 39</sup> In the initial few days following a concussion, students may need to stay home with relative restriction of physical and cognitive activities to allow acute symptoms to improve. Exacerbation of symptoms on RTS may indicate suboptimal accommodations or students pushing through symptoms. A secondary analysis of Thomas et al's study<sup>38</sup> found that symptom spikes were associated with abrupt increases in mental activity, such as school attendance and extracurricular activities, in some patients but that most students were able to RTS without symptom exacerbation.<sup>11</sup> This analysis found that symptom spikes were associated with higher symptom burdens and may be unrelated to physical or mental activity but rather other factors, such as stress or poor sleep. Conversely, some evidence indicates that longer restriction of activity, including school absence, may prolong recovery and increase symptoms.<sup>38</sup> However, the optimal length of school absence has not been determined, and is likely to vary according to type, severity and duration of symptoms. Further study of when to recommend RTS is needed to guide clinical practice.

Many review articles and consensus guidelines for RTS recommend minimising school absence to avoid possible secondary problems such as social isolation, depression and anxiety about mounting schoolwork.<sup>12–19 40 49–52</sup> These guidelines also emphasise that students do not need to be symptom-free to go back to school, although this recommendation requires further validation.<sup>12–14 18 19 40 49–52</sup> Current clinically derived, consensus-based recommendations suggest that as symptoms improve and students are able to tolerate about 30 min of cognitive activity at home without significant symptom exacerbation, they can try RTS with accommodations as needed. Return to cognitive activity/ school may be facilitated by following a stepwise, symptom-limited programme, such as the strategy proposed in the most recent concussion consensus statement (table 3).<sup>16 18 19 40 53–55</sup> Generic RTS protocols may need to be adapted to different developmental/ school levels but more research is needed in this area.<sup>56</sup>

Provision/receipt of other academic accommodations may prevent worsening of symptoms on RTS. Identification of symptom profiles and screening for specific postconcussion deficits, such as visual disturbances and vestibulo-ocular deficits, can be useful in predicting students with higher academic needs requiring symptom-targeted interventions.<sup>31</sup> <sup>41</sup> <sup>43</sup> <sup>45</sup> Specific academic accommodations, other than a period of school absence, were not examined in the reviewed studies but many guidelines, review articles and a survey of school nurses in Massachusetts list symptom-specific accommodations, <sup>12–16</sup> <sup>40</sup> <sup>49–54</sup> <sup>56</sup> <sup>57</sup> including:

- frequent breaks
- reduced workload, modified assignments
- no tests initially
- more time to complete assignments
- ▶ preferential seating in the classroom
- ▶ reduced visual and auditory stimulation.

Strategies specific to vision-related problems include avoidance of electronic screens, frequent visual breaks, preprinted notes in large font, audiobooks and oral teaching.<sup>43 45</sup>

To ensure students recovering from concussion are supported at school and receive accommodations as necessary, school personnel, parents and students need to be educated about current concussion management strategies.<sup>13 40 49 56 58-61</sup> Surveys of teachers, school principals, athletic therapists, school nurses and parents have identified that concussion education, particularly of school staff and parents, is a key factor for successfully implementing an RTS protocol.<sup>56 59-62</sup> An RCT demonstrated the effectiveness of a concussion policy as schools with an explicit policy were more likely to implement best practice guidelines for concussion management, and concussed students were more likely to receive academic accommodations after concussion.<sup>36</sup> A case study also found that schools who receive concussion education provide more academic accommodations to students after concussion and had more resources available.<sup>58</sup>

Table 3         Graduated return to school strat	egy <sup>18 55</sup>	
Mental activity	Activity at each step	Goal of each step
1. Daily activities that do not give the child symptoms	Typical activities that the child does during the day as long as they do not increase symptoms (eg, reading, texting, screen time). Start with 5–15 min at a time and gradually build up	Gradual return to typical activities
2. School activities at home	Homework, reading or other cognitive activities outside of the classroom	Increase tolerance to cognitive work
3. Return to school part-time	Gradual introduction of schoolwork. May need to start with a partial school day or with increased breaks during the day	Increase academic activities
4. Return to school full-time	Gradually progress school activities until a full day can be tolerated	Return to full academic activities and catch up on missed work

Evidence-based education programmes and online educational tools can be effective to increase knowledge of concussion and management.<sup>36 63 64</sup>

Development of school concussion policies can be guided by government legislation. The Ministry of Education in the province of Ontario, Canada, produced a policy memorandum mandating that all provincial school boards develop and implement a concussion policy.<sup>65</sup> This policy was evaluated a year after implementation in one Ontario school board by survey which found that 92% of schools have an RTP protocol and 77% of schools have an RTS protocol; however, staff training and parent education were identified as areas needing more development.<sup>61</sup> In the USA, the National Collaborative on Childhood Brain Injury recommended five areas of policy/procedural consideration to implement appropriate infrastructure to support RTS of students with concussions, including: (1) definition and training of the interdisciplinary school team; (2) professional development of school and medical communities; (3) identification, assessment and progress monitoring protocols; (4) a flexible set of intervention strategies to accommodate students' recovery needs; and (5) systematised protocols for active communication among medical, school and family team members.66

Furthermore, medical guidance can facilitate implementation of school supports for returning students. Providing explicit school-informed discharge instructions and an RTS letter after the initial concussion diagnosis in the ED resulted in significantly greater provision of academic accommodations than when not systematically recommended.<sup>39</sup> The sample letter provided (online supplementary appendix A) is recommended to ensure direct communication between the medical provider and the school regarding the student's concussion symptoms and needs. In addition, regular medical follow-up after concussion is crucial to monitor recovery and facilitate RTS. Healthcare providers should identify risk factors/modifiers, such as age and symptomatology, that may prolong recovery and necessitate more intensive accommodations.<sup>18</sup><sup>19</sup> For instance, adolescents tend to be more symptomatic and more anxious about concussion, and may require more support on RTS.<sup>29 30 34</sup>

Finally, recovery from concussion for students occurs in various arenas, including home, school, potential job and social/ sport. Effective communication between the medical team, school personnel, student and parents/caregivers is essential to ensure successful RTS for every concussed student.<sup>53 56 59-62 66</sup> Numerous surveys of various stakeholders in concussion management in students have highlighted the need for effective communication between all members of the care team.<sup>56 59-62</sup> This support network can relieve anxiety about missing school, allow students to focus on recovery and facilitate symptom improvement.<sup>13 40 49 50 58</sup> It is important to emphasise that full symptom resolution, resulting in full school reintegration, must precede full return to sport and participation in high-risk contact training and gameplay.<sup>13 14 18 19</sup> However, early introduction of symptom-limited physical activity, supervised by a qualified health professional, is appropriate and may help facilitate RTS.<sup>18</sup>

While evidence is emerging, this review highlights the lack of research to guide RTS following SRC in children and adolescents. The studies identified had high risk of bias and study designs were mostly lower levels of evidence (3 or 4); there were only two RCTs. Many questions remain unanswered, such as the optimal length of school absence following SRC and what specific accommodations should be offered. There is an urgent need for high-quality research on SRC in children and adolescents, including RTS, to better inform management guidelines.

## Limitations

RTS has been only a recent focus of concussion management and this study identified only 17 studies on this topic. The reviewed studies involved mostly high school and college students, many with mixed age cohorts (children, adolescents and adults). Despite the explosion of concussion research in the last decade, little research has been conducted in children 5–12 years of age. In addition, some studies included non-SRC and did not focus on RTS after concussion. Since we included only English language studies, these results may not be culturally generalisable and there may be language bias.

Other factors limiting generalisation of these review findings include study design, location and sample size. Level 1 evidence was not available as the majority of studies were retrospective and cross-sectional designs, with only two lower quality RCTs. Most papers had external validity and recall bias, particularly those conducted in hospital ED and specialty concussion clinics. Some studies had small sample sizes and used variable definitions of concussion and prolonged recovery. Finally, many of the studies examined school issues/outcomes at a time when there was little guidance on effective in-school management and support. With more informed guidance about RTS and provision of effective symptom-directed accommodations, RTS outcomes will likely improve.

For analysis of risk of bias, we employed the Downs and Black checklist, which was developed as a tool to be used in reviews of non-randomised studies. While we accept that the Downs and Black checklist has its limitations, and is not a perfect fit for this systematic review, it was deemed the best available for this study. An alternative risk of bias tool that would be more appropriate to the topic of RTS after paediatric concussion has yet to be developed.

## RECOMMENDATIONS

- A. Schools should have a concussion policy which includes concussion education for teachers, staff, students and parents; defines individuals within the school to direct the provision of individualised student supports; and includes a mechanism to implement and monitor appropriate academic accommodations to students recovering from SRC.
- B. On diagnosis of concussion, students should be provided with a medical letter to facilitate the provision/receipt of necessary academic accommodations.
- C. Students should have early, ongoing medical follow-up following an SRC to identify symptom targets, monitor recovery and aid with RTS, with regular communication between the medical provider, family and school.
- D. Students may require temporary absence from school after concussion. Factors such as age/grade, types and severity of symptoms should be considered in determining the length of school absence. An individualised gradual RTS plan should be considered based on recovery trajectory.
- E. Clinicians should screen for specific deficits, such as visual and vestibulo-ocular disturbances, that may affect RTS and require symptom-specific academic accommodations, as well as assess risk factors/modifiers that may prolong concussion recovery, requiring more intensive academic accommodations. In particular, adolescents may require more academic support.
- F. Future high-quality research should be conducted to determine the criteria for length of absence from school, and appropriate, individualised RTS accommodations that should be provided for children and adolescents with typically recovering and prolonged SRC symptoms.

## CONCLUSIONS

Students should rest physically and cognitively initially following a concussion with a gradual increase in activities as symptoms allow. RTS following SRC requires cooperation and communication between healthcare providers, school personnel, parents/caregivers and the student to ensure that individualised accommodations and support are provided to facilitate optimal recovery.

## What is already known?

- The effects of sport-related concussion (SRC) in children and the recovery challenges are different from adults.
- Adolescents may take longer to recover from SRC than adults and younger children.
- Return to school should be a priority in the management of children and adolescents following SRC.

### What are the new findings?

- Factors such as symptomatology, age/school level, course load and rest after injury can affect return to school following SRC.
- Schools with a concussion policy tend to offer more academic accommodations to students recovering from SRC.
- Regular medical follow-up after concussion and provision of a return to school letter can help facilitate the provision of academic support.
- Many students require a brief absence from school and academic accommodations on return to school following an SRC to avoid significant exacerbation of concussion symptoms.
